

diabetes. We aimed to assess whether there is a relationship between metabolic syndrome score and coronary artery disease angiographic severity and whether or not the severity of the relationship differs in the presence of diabetes.

Methods: We consecutively enrolled 132 metabolic syndrome patients who underwent their first coronary angiography. We used four angiographic scores and compared the relationship between metabolic syndrome score and angiographic coronary artery disease severity or clinical presentation between diabetic and non-diabetic subjects.

Results: Individuals with both metabolic syndrome and diabetes ($n=64$) had significantly higher metabolic syndrome scores, acute coronary syndromes, double and triple vessel disease, higher coronary score, extent score, severity score, and atherosclerosis score than metabolic syndrome patients without diabetes ($n=68$). A significant correlation was apparent between metabolic syndrome and coronary atherosclerotic scores in patients without diabetes. In contrast, we did not observe any significant correlation between metabolic syndrome score and coronary atherosclerotic scores in patients with diabetes. Multivariate regression analysis revealed that metabolic syndrome score is an independent predictor of atherosclerotic score in non-diabetics.

Conclusion: While the relationship between metabolic syndrome score and angiographic coronary artery disease severity was disguised by the presence of diabetes, the metabolic syndrome score was related to the extent of coronary atherosclerosis in Indian patients without diabetes. Calculating the metabolic syndrome score might provide additional information for predicting the extent of coronary artery disease in patients with angina without diabetes.

Effect of very low glycemic index diet on dyslipidemia

Omprakash Kumar, Rajiv Bajaj, Sona Abraham

Batra Hospital and Medical Research Centre, New Delhi, India

Background: The prevalence of dyslipidemia in India as per the Indian council of medical research is about 37.5% among adult age 15–64 year. Indian diets are rich in carbohydrates (in the form of Rice, Bread and Sweets). The precise role of dietary factor in genesis of dyslipidemia in our population remains to be defined. Therefore my study was aimed to see the effect of the low Glycemic Index Diet on Dyslipidemia.

Method: This study was a dietary interventional study that compared the effect of very low glycemic index diet on lipid profile over 2 month period in between January 2013 to March 2014 in subjects with dyslipidemia particularly triglyceride more than 250mg per dl.

Results: The study population was comprised of 40 subjects that include 30 males and 10 females between 26 to 70 years age group. All the subjects baseline body mass index were more than 25 kg/m² (25.1 to 40.7 kg/m²) i.e. they were overweight or obese. There were 14 diabetic (controlled by medications) and 10 hypertensive (controlled by medications) subjects. The weight and lipid profile was compared between baseline and post intervention. There was significant weight loss of 1.725 ± 1.06 Kg ($P = 0.001$), significant decrease in total cholesterol 25.32 ± 48.28 mg/dl, ($P = 0.002$), significant decrease in low density lipoprotein (LDL) cholesterol 14.2 ± 43.09 mg/dl ($P=0.044$), significant decrease in triglyceride (TG) 166.67 ± 153.64 mg/dl ($P = 0.001$), and

significant increase in high density lipoprotein (HDL) cholesterol 6.3 ± 6.3 mg/dl. There was also significant decrease of TC/HDL 1.5 ± 1.03 ($P = 0.001$), LDL/HDL 0.92 ± 1.24 ($P=0.001$), and TG/HDL 5.91 ± 4.82 ($P=0.001$).

Conclusion: Very low glycemic index diet significantly reduces body weight, total cholesterol, LDL-C, triglyceride, and increase in HDL-C. It also decreases the ratio of total cholesterol/HDL-C, LDL-C/HDL-C, and triglyceride/HDL-C. In diabetic dyslipidemic subjects, there was significant decrease of triglyceride and increase of HDL-C.

To study prevalence of diabetic neuropathy in diabetes mellitus and relation between HbA1c and QT interval

Monika Bhandari, Deepesh Venkatraman

R.G Kar Medical College & Hospital, Kolkata, India

Background: Autonomic neuropathy is frequently seen in diabetes mellitus especially in type 2 diabetes mellitus. It affects all the organ system including cardiovascular system. Cardiac autonomic neuropathy is an emerging complication of diabetes causing increasing morbidity and mortality independent of coronary artery disease which occurs frequently in diabetics. Cardiac autonomic neuropathy increases the risk of silent myocardial infarction and sudden cardiac death.

Methods: This study was done on total of 100 patients, of which 50 were diabetics and 50 non-diabetics randomized in a 1:1 fashion in case and control groups respectively. Diabetes mellitus was diagnosed using ADA definition for diabetes mellitus. Both the groups were tested for presence of cardiac autonomic neuropathy using tests for autonomic function namely, deep breath test, Valsalva's ratio, orthostatic stress test (30:15 ratio), SBP response to standing, diastolic BP response to sustained hand grip.

Results: The study showed 23(46%) diabetic patients had cardiac autonomic neuropathy as compared to only 1 patient in control group. Prevalence increases with duration of diabetes mellitus. Of 7 diabetic patients having diabetes for more than 10 years, 5(71.42%) had cardiac autonomic neuropathy. Tests of parasympathetic nervous system were more abnormal than that of sympathetic nervous system. Of 46% patients having cardiac autonomic neuropathy, 74% had QTc prolongation. QTc prolongation was directly correlated with levels of HbA1c.

Conclusion: Thus, we conclude that patients having diabetes develop cardiac autonomic neuropathy as duration of diabetes increases and test of parasympathetic function are more likely to be abnormal than that of sympathetic nervous system. Patients having cardiac autonomic neuropathy have QTc prolongation which is positively correlated with HbA1c levels.

Low educational status and greater microvascular complications in type 2 diabetes

Niharikaa Sharma, Surendra K. Sharma, Nitesh Mangal, Tripta Sharma, K.K. Sharma, Rajeev Gupta

Department of Medicine, Mahatma Gandhi Medical College, Jaipur, India

Department of Endocrinology, Galaxy Speciality Centre, Jaipur, India
Department of Medicine, Fortis Escorts Hospital, Jaipur, India

Objective: Studies from developed countries report that low socioeconomic status is associated with greater vascular complications in type 2 diabetes. To determine association of educational status (ES), as marker of socioeconomic status, with prevalence of microvascular complications in diabetes we performed a cross sectional study.

Methods: Successive patients (n=1214) presenting to this tertiary-care diabetes centre were evaluated for sociodemographic, anthropometric, clinical and therapeutic variables. Subjects were classified into 4 groups based on years of education (illiterate 216; < primary 537, < higher secondary 312, and college+ 149). Descriptive statistics are presented. Multivariate logistic regression was performed to determine association of educational status with risk factors and vascular complications.

Results: Mean age of subjects was 52+10 yr and 55% were men. Prevalence (%; 95% confidence intervals) of various risk factors was high fat diet 14.5(12.5-16.5), low fruits/vegetables 31.8(29.2-34.4), low fibre 60.0(57.2-62.7), high salt 16.9 (14.8-19.0), physical inactivity 27.5(25.0-30.0), smoking/tobacco use 25.5(23.1-27.9), overweight/obesity BMI >25 kg/m² 64.0(61.3-66.7), high waist size 63.4(60.7-66.1), hypertension 67.5(64.9-70.1), and any coronary or cerebrovascular disease 3.0(2.1-3.9). Microvascular disease (peripheral, ocular or renal) was in 20.7(18.4-23.0) and was significantly greater in illiterate (25.9, 20.1-31.7) and low (23.6, 20.0-27.2) compared to middle (15.0, 11.0-18.9) and high (14.7, 9.0-20.4) ES groups (p<0.05). In illiterate and low ES groups respectively, prevalence of smoking/tobacco use (odds ratio 3.84, 95% CI 2.09-7.05 and 2.15, 1.36-3.41); low fruit/vegetable (2.51, 1.53-4.14 and 1.99, 1.30-3.04) and low fibre intake (4.02, 2.50-6.45 and 1.78, 1.23-2.59) was greater while high waist size (0.38, 0.18-0.82 and 0.75, 0.40-1.39) and overweight (0.33, 0.20-0.53 and 0.56, 0.37-0.85) lower. Prevalence of hypertension and hypercholesterolemia was similar. Diabetes control (HbA1C >8.0) was significantly inferior in illiterate (38.0, 31.5-44.8), low (46.0, 41.8-50.2) and middle (41.0, 35.5-46.4) as compared to high (31.5, 24.0-38.9) ES subjects. In illiterate vs low, middle and high ES subjects use of more expensive medications- insulin 34.7(28.3-41.0), 30.9(27.0-34.8), 24.3(19.5-29.1) and 22.1(15.4-28.7)) and ACE inhibitors/ARBs 57.9(51.3-64.5), 53.2(49.0-57.4), 52.2(46.7-57.7) and 47.0(39.0-55.0) was significantly greater (p for trend<0.05) while use of other drugs- oral hypoglycemic and statins- was similar.

Conclusions: There is greater prevalence of microvascular disease in illiterate and low educational status diabetes patients in India. This is associated with greater prevalence of smoking/tobacco, inferior quality diet, inferior diabetes control and greater use of expensive treatments.

Congenital Heart Disease

Spectrum of cyanotic congenital heart disease in patients attending paediatric cardiology clinic of a tertiary cardiac care center

Soumya Patra, M.K. Usha, M. Jayaranganath,
Anand Subramanian, K.S. Ravindranath, C.N. Manjunath

Sri Jayadeva Institute of Cardiovascular Sciences & Research, Bangalore,
Karnataka, India

Background: Cyanotic congenital heart disease comprises up to 25% of cases of all causes of congenital heart disease. There is lack of data about the present spectrum of congenital cyanotic heart disease in paediatric age group. The present study was undertaken to determine the spectrum of patients with congenital cyanotic heart disease in paediatric age group in tertiary paediatric cardiac care clinic.

Methods: Design: Prospective observational study. Setting: Paediatric cardiac clinic of a tertiary cardiac care center. All children of 0–18 years old with suspected cyanotic congenital heart disease were provisionally included in this study. They underwent a thorough echocardiographic evaluation and those patients who had definitive diagnosis of congenital cyanotic heart disease were included for final analysis.

Results: One hundred and nineteen children met the inclusion criteria. Tetralogy of Fallot's and its variant was the most common congenital cyanotic heart disease with proportion of about 44%. Other common malformations were double outlet right ventricle (14%), pulmonary atresia with ventricular septal defect (8%), total anomalous pulmonary venous connection (7%), d-transposition of great arteries (9%), tricuspid valve anomalies (tricuspid atresia and Ebstein's anomaly), hypoplastic left heart syndrome, truncus arteriosus, and complex congenital heart disease like single ventricle.

Conclusion: Tetralogy of Fallot's or its variants was the commonest cyanotic heart disease diagnosed in our patients. As there were a significant proportion of cases with complex cyanotic congenital heart disease, so paediatric cardiologists should be familiar with the diagnosis and management of all these complex congenital malformations of heart.

Hybrid device closure of septal defects through a perthoracic incision using echo guidance

R. Ravi Kumar, K.R. Balakrishnan, N.K. Kapadia, Vijith Cherian,
Suresh Rao, B. Harapriya

Fortis Malar Hospitals, Chennai, India

Introduction: Hybrid Cardiac procedures aim at overcoming the disadvantages of Cathlab based procedures and conventional Cardiac Surgery. We propose a new approach for device closure of ASD's and Muscular VSD's using Nitinol ASD/VSD occluders through a perthoracic route.

Method: This procedure was used to close 18 ASD's and 3 VSD's in a 7 months period. Patient age range was 5 months – 45 years (Weight 7 Kg to 56 kg). The percutaneous approach for closing ASD's and VSD's in cardiac Cath lab is extremely difficult in patients weighing less than 15 KG and requires long procedure time. On the other hand, closure of ASD's and VSD's using a heart lung machine, needs long recovery period in the ICU with frequent need of blood transfusion along with full sternotomy. In the present technique the maximum ASD or VSD size was measured accurately by both TEE and TTE. Under GA, a 4–7 cm right lateral submammary incision in 4th Intercostal space (in case of ASD) or 6–7 cm lower sternal incision (in case of VSD) was made and small incision made over RA (in ASD) and RV (in case of VSD) with Purse string control of bleeding. Transthoracic preoperative Echo using sterile Jelly and TEE was used to image the defects. A 10–14 French Checkflow sheath was then passed through the defects into LA (for ASD) and LV (for VSD). Employing Transthoracic Echo Guidance, One disc of the Double disc Occluders (sized according to ASD or VSD size) was opened in LA or LV and then other disc
